Introduction: In recent years, the incidence of occupational dermatosis has increased, and their socio-economic repercussions have become significant throughout the world. In addition, there are no Moroccan statistics, yet occupational dermatosis constitute 10% of skin pathology. We have therefore developed this kit allowing a previously defined learning intended for different health professionals so that they have more information on the management of the occupational dermatosis problematic in Morocco.

Objective: The purpose of this kit is, on the one hand, to facilitate recognition of the occupational dermatoses origin and, on the other hand, to make general practitioners and specialists aware of the importance of medical monitoring of workers exposed to risks in the context of their profession while giving them the means to preserve themselves; and this is because they cover 96% of employees.

It will be important to make continuous improvements and to adapt the contents of this kit according to the evolution of science and Moroccan legislation.

Materials and Methods: The design of this kit has taken place in various stages, the most important of which are : the bibliographic research and the development of the pedagogical framework on the Node Webkit software.

Results: This kit is a computer support, which summarizes the knowledge of five themes whose logical sequence is the guiding thread of reference: a chemical, physical or biological exposure leads to a pathology recognized by its lesion group, requiring appropriate management based on Moroccan legislation.

Conclusion: This kit is a teaching tool that will allow different health professionals to manage a work-related dermatosis, to prevent their occurrence but also to repair those that are already present.
